

# HW01 Model Solutions

1. Make the following base conversions. Use shortcuts when applicable.

(a)  $101100101_2$  to decimal **357**

$$\begin{aligned}
 101100101_2 &= 1 \times 2^0 + 0 \times 2^1 + 1 \times 2^2 + 0 \times 2^3 + 0 \times 2^4 + 1 \times 2^5 + 1 \times 2^6 + 0 \times 2^7 + 1 \times 2^8 \\
 &= 1 \times 2^0 + 1 \times 2^2 + 1 \times 2^5 + 1 \times 2^6 + 1 \times 2^8 \\
 &= 1 \times 1 + 1 \times 4 + 1 \times 32 + 1 \times 64 + 1 \times 256 \\
 &= 357
 \end{aligned}$$

(b)  $101110101111010_2$  to hexadecimal **5D7A**

Conversion from binary to hex is a matter of grouping bits

$\overset{5}{\underbrace{0101}} \overset{D}{\underbrace{1101}} \overset{7}{\underbrace{0111}} \overset{A}{\underbrace{1010}}$

(c)  $101110101111010_2$  to octal **56572**

Similarly

$\overset{5}{\underbrace{101}} \overset{6}{\underbrace{110}} \overset{5}{\underbrace{101}} \overset{7}{\underbrace{111}} \overset{2}{\underbrace{010}}$

(d)  $593_{10}$  to binary **10 0101 0001**

$$\begin{array}{r|l}
 \begin{array}{r}

 \hline
 12
 \end{array} \\
 \hline
 \end{array}
 \quad
 \begin{array}{r|l}
 \begin{array}{r}
 12 \\
 -8 \\
 \hline
 4
 \end{array} & \begin{array}{r}
 8 \\
 \hline
 1
 \end{array} \\
 \hline
 \end{array}$$

(f)  $18107_{10}$  to hexadecimal **46BB**

$$\begin{array}{r|l}
 \begin{array}{r}
 18107 \\
 - 16 \\
 \hline
 21 \\
 - 16 \\
 \hline
 50 \\
 - 48 \\
 \hline
 27 \\
 - 16 \\
 \hline
 11
 \end{array}
 &
 \begin{array}{r}
 16 \\
 1131
 \end{array}
 \end{array}
 \quad
 \begin{array}{r|l}
 \begin{array}{r}
 1131 \\
 - 112 \\
 \hline
 11 \\
 - 0 \\
 \hline
 11
 \end{array}
 &
 \begin{array}{r}
 16 \\
 70
 \end{array}
 \end{array}
 \quad
 \begin{array}{r|l}
 \begin{array}{r}
 70 \\
 - 64 \\
 \hline
 6
 \end{array}
 &
 \begin{array}{r}
 16 \\
 4
 \end{array}
 \end{array}$$

(g)  $365_8$  to binary **11 110 101**

$$\begin{array}{ccc}
 \overset{3}{\underbrace{011}} & \overset{6}{\underbrace{110}} & \overset{0}{\underbrace{101}}
 \end{array}$$

(h)  $5022_8$  to decimal **2578**

$$\begin{aligned}
 5022_8 &= 2 \times 8^0 + 2 \times 8^1 + 0 \times 8^2 + 5 \times 8^3 \\
 &= 2 \times 1 + 2 \times 8 + 0 \times 64 + 5 \times 512 \\
 &= 2578
 \end{aligned}$$

(i)  $467_8$  to hexadecimal **137**

Conversion from octal to hex is a matter of regrouping bits. Requires an intermediate conversion to binary.

$$\begin{array}{ccc}
 \overset{4}{\underbrace{100}} & \overset{6}{\underbrace{110}} & \overset{7}{\underbrace{111}} \\
 \overset{1}{\underbrace{0001}} & \overset{3}{\underbrace{0011}} & \overset{7}{\underbrace{0111}}
 \end{array}$$

(j)  $D7A_{16}$  to binary **1101 0111 1010**

$$\begin{array}{ccc}
 \overset{D}{\underbrace{1101}} & \overset{7}{\underbrace{0111}} & \overset{A}{\underbrace{1010}}
 \end{array}$$

(k)  $E49F_{16}$  to decimal **58527**

$$\begin{aligned}
 E49F_{16} &= 15 \times 16^0 + 9 \times 16^1 + 4 \times 16^2 + 14 \times 16^3 \\
 &= 15 + 9 \times 16 + 4 \times 256 + 14 \times 4096 \\
 &= 15 + 144 + 1024 + 57344 \\
 &= 58527
 \end{aligned}$$

(l)  $3G2_{17}$  to 13-base notation **69A**

Convert to decimal first, and then convert to the desired base.

$$\begin{aligned}
 3G2_{17} &= 2 \times 17^0 + 16 \times 17^1 + 3 \times 17^2 \\
 &= 2 + 16 \times 17 + 3 \times 289 \\
 &= 1141
 \end{aligned}$$

$$\begin{array}{r|l}
 \begin{array}{r}
 - \begin{array}{r} 1141 \\ 104 \\ \hline 101 \\ - \quad 91 \\ \hline 10 \end{array} \\
 \end{array} & \begin{array}{r} 13 \\ 87 \end{array} \\
 \hline
 \end{array}
 \quad
 \begin{array}{r|l}
 \begin{array}{r} - \begin{array}{r} 87 \\ 78 \\ \hline 9 \end{array} \\
 \end{array} & \begin{array}{r} 13 \\ 6 \end{array} \\
 \hline
 \end{array}$$

2. What is the two's complement representation of 68 in 8-bit, 16-bit, 32-bit and 64-bit notations?.

The absolute value of the number in binary is

1000100

In order to get the two's complement representation of the number for a given number of bits, take the number and fill the remaining bits with 0.

0100 0100

0000 0000 0100 0100

0000 0000 0000 0000 0000 0000 0100 0100

0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0100 0100

Please note that the two's complement operation that consisted of flipping bits and adding one, is the equivalent of multiplying something by -1.

**No further steps are necessary for positive numbers.**

3. Convert -11 to binary using 8-bit, 16-bit, 32-bit and 64-bit two's complement notations. Have you encountered any of the values during the previous problems, and if so, where? Explain the reason the values coincide.

Take the absolute value of the number and convert to binary.

1011

Then construct the two's complement representations of the positive part.

0000 1011

0000 0000 0000 1011

0000 0000 0000 0000 0000 0000 0000 1011

0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 1011

If the given number was a positive number, **stop here.**

Steps from here onwards, apply to **negative numbers only.**

Now perform the two's complement operation on each representation in order to get the desired negative values.

Flipping the bits for each of our representations, results in:

```
1111 0100
1111 1111 1111 0100
1111 1111 1111 1111 1111 1111 1111 0100
1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 0100
```

Adding one results in

```
1111 0101
1111 1111 1111 0101
1111 1111 1111 1111 1111 1111 1111 0101
1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 0101
```

The 8-bit representation of -11, is the same as the result from 1.g, which was a positive number. These numbers are in fact two's complements of each other for 8 bits.

Please also note that an 8-bit representation of -11 in 32 bits would be

```
0000 0000 0000 0000 0000 0000 1111 0100
```

and is the original positive value.

4. Describe a model that can fully represent and store the state of the board for a game of tic tac toe in a computer. How many bytes of memory would your model require? Is your model optimal?

The board of a game of tic-tac-toe, comprises of 9 cells, each of which can contain one of the three values of X, O and empty. Each of these values needs 2 bits in order to be represented. Having 9 of these values requires a total of 18 bits, but since the unit for storing information is a byte, the model requires 3 whole bytes even though there are 6 unused bits.

While this model is fully sufficient as a stand-alone solution for practical purposes, there are ways to reduce the memory footprint of board representation at the expense of some calculation and a lot of memory overhead.

There is a total of  $3^9 = 19683$  ways to fill the board which is well under 65536, 2 bytes. So, if we assigned a unique identifier number to each of these arrangements and also stored all the possible arrangements in a look-up table, we could represent a running game in under 2 bytes.

It should be noted that this number includes a large amount of invalid formations, such as a board filled with all X. Eliminating those and only keeping track of legal boards would shrink our total number significantly, but nowhere near less than 1 byte.

Since a lot of people were curious, I am sharing this combinatorical calculation for the total number of unique boards for a starting X, including winning arrangements. In essence, it goes as follows:

$$\binom{9}{1} + \binom{9}{1}\binom{8}{1} + \binom{9}{2}\binom{7}{1} + \binom{9}{2}\binom{7}{2} + \binom{9}{3}\binom{6}{2} + \binom{9}{3}\binom{6}{3} + \binom{9}{4}\binom{5}{3} + \binom{9}{4}\binom{5}{4} + \binom{9}{5}\binom{5}{4} = 6549$$

Once the game-over boards are out of the picture, this number can be reduced even further if semantically identical arrangements are discarded as well. Arrangements are considered equivalent, if they can be derieved from a base arrangement through rotation and mirroring. There are 756 base arrangements in total.

## 5. Is it possible to play console games (such as those made for PlayStation) on a PC? How?

IBM compatible computers (almost every PC not recently made by Apple) rely on Intel architecture (Intel and AMD chips). If a console also uses the same architecture, then the binary executables made for those consoles can run on that PC, natively. However, there are always additional software dependencies that impose further limitations and that is why Windows programs will not run on Linux without workarounds, even though they are running on the same hardware.

If the console has a different architecture (Play Station), then the short answer is no. A binary executable made for a different architecture will only run on that platform.

The long answer, however, includes software solutions that "emulate" other platforms, making executables "feel" as if they are in their native environment, and translate the binary instructions with some performance pentalty. This approach is often used during development for making these games and various applications in the first place and for testing and debugging them.

Sometimes, developers opt for embedding an emulator in the program itself in order to reduce their efforts, at the expense of some loss of functionality.

In case you were curious, this document was produced using L<sup>A</sup>T<sub>E</sub>X

$$\hat{A}_b(\gamma) = - \int_0^\infty \frac{x^{e^x}}{\sqrt{1 - \frac{\phi^2}{\theta^2}}} \partial \sigma K_L e(\tau) d\sigma \quad (1)$$
